

# SuperCorona, the Best Solution for Smooth Surfaces

- In a Corona gun the high voltage electrode generates a big quantity of ions. Only a few ions charge the powder particles, the others remain free and are attracted by the part surface.
- The accumulation of ions on the part surface can produce “**orange peel effect**” and “**back-ionization**” problems.
- SuperCorona discharges the excessive free ions and significantly **improves the surface quality**.
- The free ions generate a strong electric field that makes it more difficult for powder to penetrate into corners and recesses (**Faraday Cage Effect**).
- SuperCorona discharges the excessive free ions and **facilitates the powder penetration**.

Controlled  
Powder Charging

Improved  
Surface Quality

Increased Powder  
Penetration

# PCC Mode, the Perfect Control on Powder Charging

- Most common powders need the gun to deliver a **high level of charging current** (10 to 100  $\mu\text{A}$ ).
- Special powders (metallic, enamel, two coat / one fire powders) are high-chargeable and require the guns to deliver a lower and **well controlled charging current**, below 10  $\mu\text{A}$ .
- Gema Precise Charge Control (**PCC technology**) allows to control powder charging very precisely, with a resolution of only 0.5  $\mu\text{A}$  until 10  $\mu\text{A}$ .
- This is the ideal solution to provide the right amount of charges and achieve a **much better application quality**.

Precise  
Powder Charging

Improved  
Surface Quality

Ideal for  
Special Powders

# Electrostatic Powder Coating

- Today's powder coaters need to use a wide variety of powders, with different formulations and characteristics.
- Only the ideal charging of each powder ensures perfect coating results.
- Gema is offering innovative technologies to achieve the ideal charging of even challenging powders like structured and metallic powders, porcelain enamel, 2-coats 1-fire powders, etc.

# Corona Charging: How Does it Work?

- In a **corona gun** the high voltage electrode generates a big quantity of air ions
- Only part of the air ions really charge the powder particles, the other ions remain free and are attracted by the surface to coat (which is grounded).
- The accumulation of free ions on the surface to coat can produce an uneven powder layer and the so called "**orange peel effect**" or "**back-ionization**" problems.

# SuperCorona: How Does it Work?

- SuperCorona is an add-on accessory that can be easily mounted on any Gema gun.
- It can significantly improve **surface quality** and **powder penetration**, both for manual and for automatic guns.
- It can be removed for the powders that don't need it.

# Precise Charge Control: How Does it Work?

## Traditional Charging: less precise, low resolution

- In traditional corona guns the regulations of the electrostatic parameters are not very precise.
- The actual value of the charging current can vary within a significant range in comparison to the set value.
- The parameters can be set only with a relatively large resolution (1  $\mu\text{A}$  / 1 kV or more)

## Precise Charge Control (PCC): more precise, high resolution

- Gema has developed PCC, an electronic technology that allows more precise electrostatic regulations.
- The electrostatic parameters are kept within a much smaller variation band in comparison to the set values
- The parameters can be set with a smaller resolution (0.5  $\mu\text{A}$ ) and controlled much more precisely

# Precise Charge Control Activation

- **Precise Charge Control (PCC)** mode is automatically activated when Current is set below 10  $\mu\text{A}$ .
- The OptiSpray display showing the High Voltage and Current control turns red when PCC mode activates.

# Improved Surface Quality

- Orange peel effect and back-ionization can happen when the guns are emitting too much charges. These charges accumulate on the surface to coat and create visual defects.
- **PCC** technology and **SuperCorona** help to optimize the amount of charges that are needed by each powder.

## Results

- **much nicer surfaces,**
- **even with special powders,**
- **even when high film thicknesses are needed**

# Improved Powder Penetration

- Powder penetration into corners is difficult because of the Faraday Cage effect.
- The electric field (created by the electrode and by the charges) pushes powder particles to the edges of the object, while the electric field is not getting into the corners.
- **PCC technology** and **SuperCorona** reduce the electric field generated by the free ions.

## Results

- **Easier penetration into corners**
- **More regular powder distribution**
- **Powder savings**
